# COUNTING CURVES
# AND THEIR PROJECTIONS

### Joachim von zur Gathen,
### Marek Karpinski and Igor Shparlinski

**Abstract.** Some deterministic and probabilistic methods are presented for counting and estimating the number of points on curves over finite fields, and on their projections. The classical question of estimating the size of the image of a univariate polynomial is a special case. For curves given by sparse polynomials, the counting problem is $\#\mathcal{P}$-complete via probabilistic parsimonious Turing reductions.

## 1. Introduction

One of the most celebrated results in algebraic geometry is Weil's theorem on the number of points on algebraic curves over a finite field. In this paper, we address some computational problems related to this question.

Our main results are:

o A "computational Weil estimate" for projections of curves and images of polynomials, in Section 3.

o $\#\mathcal{P}$-completeness of the exact counting problem for sparse curves, in Section 4.

We consider a finite field $\mathbb{F}_q$ with $q$ elements, an algebraic closure $K$ of $\mathbb{F}_q$, a polynomial $f \in \mathbb{F}_q[x, y]$ of degree $n$ , the plane curve $\overline{\mathcal{C}} = \{f = 0\} = \{(a, b) \in K^2 : f(a, b) = 0\}$ of genus $g \leq (n-1)(n-2)/2$ defined over $\mathbb{F}_q$, and the number $N_k(\overline{\mathcal{C}}) = \#(\overline{\mathcal{C}} \cap \mathbb{F}_{q^k}^2)$ of rational points on $\overline{\mathcal{C}}$ over $\mathbb{F}_{q^k}$. We assume that $f$ is squarefree, so that $\overline{\mathcal{C}}$ is reduced, but $\overline{\mathcal{C}}$ may be reducible or have singular points. Our focus is on studying the curve $\mathcal{C} = \overline{\mathcal{C}} \cap \mathbb{F}_q^2 = \{(a, b) \in \mathbb{F}_q^2 : f(a, b) = 0\}$ in $\mathbb{F}_q^2$. Most of our methods would also work for projective curves, but we restrict to the affine case, except in this Introduction and Section 6.

The only general information about the numbers $N_k(\overline{\mathcal{C}})$ is Weil's fundamental result that for an absolutely irreducible smooth projective curve $\overline{\mathcal{C}}$ of genus $g$

over $\mathbb{F}_q$ there are algebraic integers $\vartheta_1, \ldots, \vartheta_g \in \mathbb{C}$—the *Frobenius roots*—with absolute values $|\vartheta_i| = q^{1/2}$ for $1 \leq i \leq g$ such that

$$N_k(\overline{\mathcal{C}}) = q^k + 1 - \sum_{1 \leq i \leq g} (\vartheta_i^k + \bar{\vartheta}_i^k); \tag{1.1}$$

in particular, this implies the *Weil estimate*

$$|N_k(\overline{\mathcal{C}}) - q^k - 1| \leq 2gq^{k/2}. \tag{1.2}$$

Recall that $f \in \mathbb{F}_q[x, y]$ is *absolutely irreducible* if it is irreducible in $K[x, y]$. $\mathcal{C} = \{f = 0\}$ is *smooth* if there are no solutions to $f = \partial f / \partial x = \partial f / \partial y = 0$, and a *projective* curve includes points at infinity. Any text on algebraic geometry, such as Shafarevich (1974) or Hartshorne (1977), explains these notions, and Appendix C in the latter text gives a highly readable exposition of Weil's results and their far-reaching generalizations.

Some improvements on the Weil estimate—exploiting the algebraic nature of the Frobenius roots—are in Serre (1983a, 1983b), and Shparlinski (1992a), Chapter 5. Vladut & Drinfeld (1983) show $N_1(\overline{\mathcal{C}}) \leq g(q^{1/2} - 1) + o(g)$ for curves of large genus over a fixed field; this is twice better than the Weil estimate. Fried & Jarden (1986, Theorem 4.9) and Bach (1996) show that some variants of (1.2) hold for absolutely irreducible projective curves even if they are singular. Bach shows that (1.2) holds for the arithmetic genus $g$, which also satisfies $g \leq (n-1)(n-2)/2$.

The first question addressed in this paper is the *curve size problem*: Can we find an approximation to $N_k(\overline{\mathcal{C}})$ that is better than the Weil estimate? We deal with an affine plane curve $\mathcal{C}$; for problems like curve counting, it is easy to pass to the projective case, and also to curves given in a higher dimensional space. The ultimate goal would be a deterministic algorithm that calculates $N_k(\overline{\mathcal{C}})$ exactly and runs in polynomial time $(nk \log q)^{O(1)}$; it is not clear at all whether this goal can be attained. "Time" will usually mean arithmetic operations in $\mathbb{F}_q$; the number of bit operations is at most a factor $O\tilde{\ }(\log q)$ larger, where the "soft-$O$" notation $s = O\tilde{\ }(t)$ means that $s = t \cdot (\log t + 2)^{O(1)}$.

Pila (1990) presented an algorithm for calculating $N_k(\overline{\mathcal{C}})$ that generalized Schoof's (1985) method, which applies to elliptic curves. The computing time of Pila's algorithm is $(k \log q)^{\Delta(n)}$, where $\Delta(n)$ is a doubly exponential function of $n$. Since the first version of the present paper appeared, Huang & Ierardi (1993) have given a probabilistic algorithm with running time as above, but with $\Delta(n) = n^{O(1)}$.

For the related problem of counting the number of zeros of a multivariate sparse polynomial over a "small" finite field some probabilistic approximation

algorithms are known; see Grigoryev & Karpinski (1991) and the references there.

Section 2 introduces a "strip counting" method. It is based on the principle that the behaviour of a curve over a wide enough "strip" is the same as over the whole field, and uses Bombieri's (1966) bound on exponential sums along a curve. We use it to count the number of absolutely irreducible components defined over $\mathbb{F}_q$, and to get a size estimate from Weil's estimate.

The second question of this paper is the *projection size problem*: determine the number of points in the image of the projection $\pi : \overline{\mathcal{C}} \to \mathbb{F}_q$ onto the first coordinate, and in fact the number $r_i$ of points in $\mathbb{F}_q$ with exactly $i$ preimages under $\pi$. Section 3 presents a "computational Weil estimate" of the form

$$|r_i - \lambda_i q| = O(q^{1/2}), \tag{1.3}$$

with $\lambda_i \in \mathbb{Q}$, and a "strip counting" method for computing $\lambda_i$. This is "computational" in the sense that the classical Weil estimate (1.2)—for a different problem—sets $\lambda_i = 1$, without any computation; see also Fried & Jarden (1986), paragraph 5, for related estimates. Both the computing time and the constant implied in (1.3) depend exponentially on $n$, and $q$ has to be prime for "strip counting".

We apply this result to the important problem of counting the number of points with a fixed number of preimages under a univariate polynomial or rational function. A special case of our resulting formula, namely for the total image size of a polynomial, is essentially in Birch & Swinnerton-Dyer (1959).

In Section 4, we show that curve counting is $\#\mathcal{P}$-complete via probabilistic Turing reductions if the defining polynomial $f \in \mathbb{F}_q[x, y]$ is given in sparse representation. This is based on efficient methods, due to McCurley and Alford, Granville & Pomerance, for finding primes in certain arithmetic progressions. The basic tool is a reduction from certain gcd problems for sparse polynomials over $\mathbb{Z}$ for which Plaisted (1977) proved $\mathcal{NP}$-hardness and Quick (1986) $\#\mathcal{P}$-hardness. In those papers, membership in $\mathcal{NP}$ or $\#\mathcal{P}$ was left as an open question. This is answered affirmatively for the curve counting problem, and as a consequence we also solve this open question for the special variant of the gcd problem that we consider.

In Section 5, we reduce the general curve counting problem to that of absolutely irreducible curves—that is the case to which the Weil estimate applies. In Section 6, we show how to compute $N_k(\overline{\mathcal{C}})$ quickly in the case of "small" $n$ and $q$ and "large" $k$; in all other sections we restrict to the case $k = 1$. Section 7 gives an approximation scheme. This provides estimates also for "large" $n$, where the Weil estimate gives no information. In Section 8, we introduce a

deterministic method to estimate the image size of special polynomial mappings $\mathbb{F}_{q^k}^m \to \mathbb{F}_q$; this method is particularly useful when $k$ is large. It yields an algorithm to determine whether an Artin–Schreier curve given by a sparse polynomial has a rational point over $\mathbb{F}_q$.

Throughout the paper, we use $\mathsf{M}(k)$ to denote an upper bound on the cost of multiplication, so that polynomials in $R[x]$ of degree at most $k$ can be multiplied with $O(\mathsf{M}(k))$ operations in $R$, for any ring $R$. We may use $\mathsf{M}(k) = k^2$ for "classical arithmetic", and $\mathsf{M}(k) = k \log k \log\log k$ for "fast arithmetic". If $R \subseteq R[y]/(f) = S$ is an extension of degree $m$, then one can multiply in $S[x]$ with $O(\mathsf{M}(mn))$ operations in $R$ (see von zur Gathen & Shoup 1992, Lemma 2.2). All logarithms in this paper are natural.

## 2. Estimating the size of a curve over a prime field

We propose a deterministic "strip counting" algorithm to estimate the size of curves over a prime field $\mathbb{F}_q$. It relies on the general principle that the "behaviour" of a curve or an algebraic variety over a wide enough "strip" is the same as over the whole field; Shparlinski (1992b) gives another example of using this principle.

We will use the following notation: $K$ is an algebraic closure of $\mathbb{F}_q$, $\overline{\mathcal{C}} \subseteq K^{m+1}$ is an affine curve of degree $n$, $\mathcal{C} = \overline{\mathcal{C}} \cap \mathbb{F}_q^{m+1}$ are the rational points of $\overline{\mathcal{C}}$ over $\mathbb{F}_q$. Often we concentrate on plane curves $\overline{\mathcal{C}} = \{(a, b) \in K^2 : f(a, b) = 0\}$ given by $f \in \mathbb{F}_q[x, y]$ of total degree $n$.

Since we are interested in counting the size of curves, we assume that they are *reduced*, i.e., without multiple components; for a plane curve $\mathcal{C} = \{f = 0\}$, this means that $f$ is squarefree.

For an absolutely irreducible affine curve $\mathcal{C} \subseteq \mathbb{F}_q^{m+1}$, (1.2) implies that

$$|\#\mathcal{C} - q| \leq n^2 q^{1/2}, \tag{2.1}$$

since

$$|\#\mathcal{C} - q| \leq 2\frac{(n-1)(n-2)}{2}q^{1/2} + n + 1 \leq n^2 q^{1/2}.$$

The last inequality holds for $n \geq 2$, but (2.1) is obviously true also for $n = 1$.

A curve $\mathcal{C}$ that is reduced and irreducible over $\mathbb{F}_q$ and not absolutely irreducible is called *exceptional*. (Recall that this means that the ideal of $\mathcal{C}$ in $\mathbb{F}_q[x_1, \ldots, x_{m+1}]$ is prime and the corresponding ideal in $K[x_1, \ldots, x_{m+1}]$ is not prime.) The following bound is probably well–known.

LEMMA 2.1. *For an exceptional curve* $\mathcal{C} \subseteq \mathbb{F}_q^{m+1}$ *of degree* $n$ *we have* $\#\mathcal{C} \leq n^2/4$.

PROOF.     The ideal of $\mathcal{C}$ is the product of at least two distinct prime ideals in $K[x_1, \ldots, x_{m+1}]$. Each point of $\mathcal{C}$ lies on the intersection of the corresponding curves over $K$, which has at most $n^2/4$ points, by Bézout's Theorem.     □

An explicit version of this statement for plane curves is given in Lemma 5.2, where also all points of $\mathcal{C}$ are computed.

For a set $S \subseteq \mathbb{F}_q^m$ and $A \subseteq \mathbb{F}_q$, we write

$$S(A) = S \cap (A \times \mathbb{F}_q^{m-1}) \tag{2.2}$$

for the set of points in $S$ over $A$. The crucial ingredient for our "strip-counting" is the following consequence of Bombieri's (1966) bound on exponential sums along a curve.

LEMMA 2.2. *Let* $p$ *be a prime, and* $\mathcal{C} \subseteq \mathbb{F}_p^{m+1}$ *a curve of degree* $n < p$ *over* $\mathbb{F}_p$ *none of whose absolutely irreducible components defined over* $\mathbb{F}_p$ *is contained in a hyperplane* $\{a\} \times \mathbb{F}_p^m$ *with* $a \in \mathbb{F}_p$. *Furthermore, let* $0 < h \leq p$ *and* $A = \{0, \ldots, h-1\} \subseteq \mathbb{F}_p$. *Then the number* $\#\mathcal{C}(A)$ *of points on* $\mathcal{C}$ *over* $A$ *satisfies*

$$|\#\mathcal{C}(A) - h\#\mathcal{C}/p| \leq ((n^2 - n)p^{1/2} + n^2)\log p,$$

*and if* $n \leq p^{1/2}$, *then*

$$|\#\mathcal{C}(A) - h\#\mathcal{C}/p| \leq n^2 p^{1/2} \log p.$$

PROOF.     We have

$$\#\mathcal{C}(A) = \frac{1}{p} \sum_{(a_1, \ldots, a_m) \in \mathcal{C}} \sum_{0 \leq u < p} \sum_{0 \leq v < h} \exp(2\pi i u(a_1 - v)/p).$$

Rearranging the sum and separating the term $h\#\mathcal{C}/p$ corresponding to $u = 0$, we get

$$\#\mathcal{C}(A) - h\#\mathcal{C}/p = \frac{1}{p} \sum_{1 \leq u < p} \sum_{(a_1, \ldots, a_m) \in \mathcal{C}} \exp(2\pi i u a_1/p) \sum_{0 \leq v < h} \exp(-2\pi i u v/p).$$

The bound of Bombieri (1966), Theorem 6, on exponential sums along a curve implies for $1 \leq u < p$ that

$$\left| \sum_{(a_1, \ldots, a_m) \in \mathcal{C}} \exp(2\pi i u a_1/p) \right| \leq (n^2 - n)p^{1/2} + n^2.$$

Using this bound and the well-known inequality

$$\sum_{1 \leq u < p} \left| \sum_{0 \leq v < h} \exp(2\pi i u v / p) \right| < p \log p$$

(see e.g., Vinogradov 1981, Exercise 11.c for chapter 3, p. 52), we get

$$|\#\mathcal{C}(A) - h \#\mathcal{C}/p| < ((n^2 - n)p^{1/2} + n^2) \log p. \quad \square$$

We say that a curve in $\mathbb{F}_q^{m+1}$ is *without vertical components* (over $\mathbb{F}_q$) if and only if it has no absolutely irreducible components defined over $\mathbb{F}_q$ in a hyperplane $\{a\} \times \mathbb{F}_q^m$ for any $a \in \mathbb{F}_q$, and say *without vertical lines* if $m = 1$. This condition is necessary for the estimate of Lemma 2.2 to be valid. In general, it is not clear to us how to check efficiently for it. However, for a plane curve $\mathcal{C}$ given by $f \in \mathbb{F}_q[x, y]$, we can compute the content $c = \mathrm{cont}_y(f) \in \mathbb{F}_q[x]$, and then $\mathcal{C}' = \{f/c = 0\}$ has no vertical lines. The vertical lines in $\mathcal{C}$ are precisely the lines $\{a\} \times \mathbb{F}_q$, where $a \in \mathbb{F}_q$ is a root of $c$. Given the number of absolutely irreducible components or (an estimate for) the number of points on $\mathcal{C}'$, it is easy to compute the corresponding quantity for $\mathcal{C}$. In the sequel, we will often assume that $\mathcal{C}$ is without vertical lines.

LEMMA 2.3. *Let* $\mathcal{C} \subseteq \mathbb{F}_q^{m+1}$ *be a reduced curve of degree* $n$ *without vertical components,* $\mathcal{C}_1, \ldots, \mathcal{C}_\sigma$ *the absolutely irreducible components of* $\mathcal{C}$ *that are defined over* $\mathbb{F}_q$, *and* $A \subseteq \mathbb{F}_q$. *Then*

$$|\#\mathcal{C}(A) - \sum_{1 \leq i \leq \sigma} \#\mathcal{C}_i(A)| \leq n^2/2.$$

PROOF.    We decompose $\mathcal{C}$ into its irreducible components over $\mathbb{F}_q$:

$$\mathcal{C} = \mathcal{C}_1 \cup \cdots \cup \mathcal{C}_\sigma \cup \mathcal{C}_{\sigma+1} \cup \cdots \cup \mathcal{C}_\tau,$$

where $\mathcal{C}_{\sigma+1}, \ldots, \mathcal{C}_\tau$ are not absolutely irreducible, and let $n_i = \deg \mathcal{C}_i$ for $i \leq \tau$, so that $n = \sum_{1 \leq i \leq \tau} n_i$. Bézout's Theorem and Lemma 2.1 imply that

$$\#(\mathcal{C}_i(A) \cap \mathcal{C}_j(A)) \leq \#(\mathcal{C}_i \cap \mathcal{C}_j) \leq n_i n_j \text{ for } 1 \leq i < j \leq \sigma,$$

$$\#\mathcal{C}_i(A) \leq \#\mathcal{C}_i \leq n_i^2/4 \text{ for } \sigma < i \leq \tau.$$

Thus we have

$$\begin{aligned} \sum_{1 \leq i \leq \sigma} \#\mathcal{C}_i(A) - \#\mathcal{C}(A) &\leq \sum_{1 \leq i < j \leq \sigma} \#(\mathcal{C}_i(A) \cap \mathcal{C}_j(A)) \\ &\leq \sum_{1 \leq i < j \leq \sigma} n_i n_j \leq n^2/2, \end{aligned}$$

$$\#\mathcal{C}(A) - \sum_{1 \le i \le \sigma} \#\mathcal{C}_i(A) \; \le \; \sum_{\sigma < i \le \tau} \#\mathcal{C}_i(A)$$

$$\le \; \sum_{\sigma < i \le \tau} n_i^2/4 \; \le \; n^2/4. \qquad \square$$

THEOREM 2.4. *Let $p$ be a prime, $\mathcal{C} \subseteq \mathbb{F}_p^{m+1}$ a curve of degree $n \le p^{1/2}$ with exactly $\sigma$ absolutely irreducible components that are defined over $\mathbb{F}_p$ and without vertical components, $0 < h \le p$, and $A = \{0, \ldots, h-1\} \subseteq \mathbb{F}_p$. Then*

(i) $|\#\mathcal{C}(A) - h\#\mathcal{C}/p| \le n^2 + n^2 p^{1/2} \log p < 2.03\, n^2 p^{1/2} \log p,$

(ii) $|\#\mathcal{C}(A) - \sigma h| \le n^2(1/2 + p^{1/2} + p^{1/2} \log p) < 3\, n^2 p^{1/2} \log p.$

PROOF.     (i) Let $\mathcal{C}_1, \ldots, \mathcal{C}_\sigma \subseteq \mathbb{F}_p^{m+1}$ be the absolutely irreducible components of $\mathcal{C}$ that are defined of $\mathbb{F}_p$, and $n_i = \deg \mathcal{C}_i$ for $i \le \sigma$, so that $\sum_{1 \le i \le \sigma} n_i \le n$. Using Lemmas 2.2 and 2.3, we have

$$|\#\mathcal{C}(A) - h\#\mathcal{C}/p|$$
$$\le \; |\#\mathcal{C}(A) - \sum_{1 \le i \le \sigma} \#\mathcal{C}_i(A)| + \sum_{1 \le i \le \sigma} |\#\mathcal{C}_i(A) - h/p \cdot \#\mathcal{C}_i|$$
$$+ \, h/p \cdot | \sum_{1 \le i \le \sigma} \#\mathcal{C}_i - \#\mathcal{C}|$$
$$\le \; n^2/2 + \sum_{1 \le i \le \sigma} n_i^2 p^{1/2} \log p + h/p \cdot n^2/2$$
$$\le \; n^2 + n^2 p^{1/2} \log p \; < \; 2.03\, n^2 p^{1/2} \log p,$$

since $1 < 1.03\, p^{1/2} \log p$ for $p \ge 2$. For (ii), we have from Lemmas 2.3 and 2.2, and (2.1), applied to the absolutely irreducible curves $\mathcal{C}_1, \ldots, \mathcal{C}_\sigma$, that

$$|\#\mathcal{C}(A) - \sigma h| \; \le \; |\#\mathcal{C}(A) - \sum_{1 \le i \le \sigma} \#\mathcal{C}_i(A)|$$
$$+ \; \sum_{1 \le i \le \sigma} |\#\mathcal{C}_i(A) - h/p \cdot \#\mathcal{C}_i| + h/p \cdot \sum_{1 \le i \le \sigma} |\#\mathcal{C}_i - p|$$
$$\le \; n^2/2 + p^{1/2} \log p \sum_{1 \le i \le \sigma} n_i^2 + h/p \cdot n^2 p^{1/2}$$
$$\le \; n^2(1/2 + p^{1/2} + p^{1/2} \log p) \; < \; 3\, n^2 p^{1/2} \log p. \quad \square$$

We will repeatedly use a "brute force" method for computing $\#\mathcal{C}(A)$, where $\mathcal{C} = \{f = 0\} \subseteq \mathbb{F}_{q^k}^2$, namely, by calculating

$$\deg \gcd(f(a, y), y^{q^k} - y) = \#\mathcal{C}(\{a\}) \tag{2.3}$$

for all $a \in A$, and summing up. To estimate the time for this, we let $\mathsf{MM}(n)$ denote the cost of $n \times n$-matrix multiplication, so that $\mathsf{MM}(n) = O(n^{2.376})$ (Coppersmith & Winograd 1990).

LEMMA 2.5. Let $n, m, k \geq 1$, $f \in \mathbb{F}_q[x, y]$ have degree $n$, $\mathcal{C} = \{f = 0\} \subseteq \mathbb{F}_{q^k}^2$, and $A \subseteq \mathbb{F}_{q^m} \subseteq \mathbb{F}_{q^k}$. Then we can compute $\#\mathcal{C}(A)$ with

$$O\Big(\#A \cdot \mathsf{M}(m)(1 + \log m) \cdot (\mathsf{M}(n) \log(nq) + n^{1/2} \log k[\mathsf{M}(n) + \mathsf{MM}(n^{1/2})])\Big)$$

$$\text{or } \tilde{O}(\#A \cdot m \cdot (n \log q + n^{1.7} \log k))$$

operations in $\mathbb{F}_q$, and when $k = m = 1$, with only

$$O(\#A \cdot \mathsf{M}(n) \log(nq))$$

operations.

PROOF.    For each $a \in A$, we can compute $y^{q^k} \bmod f(a, y)$ with

$$O(\mathsf{M}(n) \log q + n^{1/2} \log k[\mathsf{M}(n) + \mathsf{MM}(n^{1/2})])$$

operations in $\mathbb{F}_{q^m}$ (von zur Gathen & Shoup 1992, Lemma 5.3), and the gcd in (2.3) with $O(\mathsf{M}(n) \log n)$ operations. $\square$

Actually, this method even computes the set $\mathcal{C}(A)$. In particular, the "brute force" method of calculating $N_k(\overline{\mathcal{C}})$, with $A = \mathbb{F}_{q^k}$, can be executed with $\tilde{O}(nq^k)$ operations in $\mathbb{F}_q$.

COROLLARY 2.6. Let $p$ be a prime, $\mathcal{C} \subseteq \mathbb{F}_p^2$ have degree $n$, $\epsilon > 0$, and set $r = p^{1/2}/(2.03 \log p)$.

(i) We can compute an approximation $\gamma$ to $\#\mathcal{C}$ satisfying

$$|\#\mathcal{C} - \gamma| \leq \epsilon p$$

with $\tilde{O}(\epsilon^{-1} n^3 p^{1/2})$ operations in $\mathbb{F}_p$ if $n^2 \leq \epsilon r$, and $\tilde{O}(np)$ operations otherwise.

*(ii) If $n^2 \leq r/5$, then we can compute the number of absolutely irreducible components of $\mathcal{C}$ defined over $\mathbb{F}_p$ with $\tilde{O}(n^3 p^{1/2})$ operations in $\mathbb{F}_p$.*

PROOF. We may assume that $\mathcal{C}$ has no vertical lines. For (i), we set $h = \lceil 2.03\,\epsilon^{-1} n^2 p^{1/2} \log p \rceil$. If $n^2 > \epsilon r$, so that $h > p$, we apply Lemma 2.5 with $p = q$, $m = k = 1$ and $A = \mathbb{F}_p$ to compute $\#\mathcal{C}$ exactly, with $O(pM(n)\log(np))$ operations in $\mathbb{F}_p$. Otherwise, we set $A = \{0, \ldots, h-1\} \subseteq \mathbb{F}_p$, compute $\#\mathcal{C}(A)$ by Lemma 2.5 with $O(hM(n)\log(np))$ operations in $\mathbb{F}_p$, and return $\gamma = p\#\mathcal{C}(A)/h$. The claim follows from Theorem 2.4 (i).

(ii) Let $\sigma$ be the number of these components, let $\epsilon = 1/3$, and $h = \lceil 9n^2 p^{1/2} \log p \rceil$. Since $h \leq p$, we have from Theorem 2.4 (ii)

$$|\#\mathcal{C}(A)/h - \sigma| \leq 1/3,$$

so that it is easy to determine the integer $\sigma$. $\square$

In Theorem 5.3 below we give a different (probabilistic) algorithm which is faster than the one of Corollary 2.6 if $n$ is small and $p$ is large.

## 3. Estimating the size of a projection

In this section, we present an algorithm to estimate the size of the projection of a plane curve, and the size of the image of a univariate polynomial.

Let $\mathcal{C} = \{f = 0\} \subseteq \mathbb{F}_q^2$ be a curve without vertical lines, given by $f \in \mathbb{F}_q[x, y]$ of degree $n$, and let

$$\pi : \mathcal{C} \to \mathbb{F}_q \qquad\qquad (3.1)$$

be the first projection, with $\pi((a, b)) = a$. Furthermore, let $A \subseteq \mathbb{F}_q$, $i \in \mathbb{N}$, and define

$$R_i(A) = \{a \in A : \#\pi^{-1}(\{a\}) = i\}, \quad r_i(A) = \#R_i(A). \qquad (3.2)$$

We are interested in the two cases where $A = \mathbb{F}_q$, or where $q$ is a prime and $A = \{0, \ldots, h-1\}$ for some $h$ near $q^{1/2}$. Since $A$ is fixed for most of this section, we usually write $R_i$ and $r_i$.

For our task, it is sufficient to determine the more informative $r_1, \ldots, r_n$, since the size of the projection satisfies

$$\#\pi(\mathcal{C}) = \sum_{1 \leq i \leq n} r_i. \qquad\qquad (3.3)$$

The idea is to reduce the determination of $r_i$ to the size of certain associated curves $S_1, \ldots, S_n$. Then an estimate of $\#S_k$ à la Weil, with an error term

$O(q^{1/2})$, will lead to an estimate of the $r_i$'s with error $O(q^{1/2})$; we call this a "computational Weil estimate". The constants implied in the Big-Oh depend exponentially on $n$.

We may assume that the defining polynomial $f$ is squarefree, since repetitions of factors do not change $\mathcal{C}$, and we can easily compute the squarefree part of an arbitrary $f$. Furthermore, we may assume that $\mathcal{C}$ contains no vertical lines; thus $R_i = \emptyset$ for $i > n$.

For $1 \leq k \leq n$, let

$$S_k = \{(a_0, a_1, \ldots, a_k) \in \mathbb{F}_q^{k+1} : f(a_0, a_1) = \cdots = f(a_0, a_k) = 0,$$
$$a_i \neq a_j \text{ for } 1 \leq i < j \leq k\},$$
$$s_k = \#S_k.$$

The geometry of $S_2$ is discussed in von zur Gathen & Shparlinski (1995). Here we need the following statement.

LEMMA 3.1. *If the curve $\mathcal{C}$ does not contain a vertical line, then no absolutely irreducible component of any $S_k$ for $1 \leq k \leq n$ is vertical.*

PROOF.      Assume that an absolutely irreducible component $\mathcal{D}$ of $S_k$ is contained in $\{a\} \times \mathbb{F}_p^{k+1}$ for some $a \in \mathbb{F}_p$. Then there is a projection $\pi_i \colon \mathbb{F}_p^{k+2} \to \mathbb{F}_p^2$ with

$$\pi_i(a_0, a_1, \ldots, a_k, b) = (a_0, a_i)$$

for some $i \leq k$ such that $\pi_i(\mathcal{D})$ is a curve; but then its closure is a vertical component of $\mathcal{C}$, contradicting our assumption. $\square$

Under the surjective map $S_k \to \bigcup_{k \leq i \leq n} R_i$ with $(a_0, \ldots, a_k) \mapsto a_0$, each $a \in R_i$ has exactly $i_{(k)}$ images, where $i_{(k)} = i \cdot (i-1) \cdots (i-k+1)$ is the Pochhammer symbol. Thus

$$s_k = \sum_{k \leq i \leq n} i_{(k)} r_i \quad \text{for } 1 \leq k \leq n. \tag{3.4}$$

We now show how to determine the $r_i$'s explicitly from the $s_k$'s, using (3.4) and an inclusion–exclusion principle, then how to obtain approximations for the $r_i$'s from approximations to the $s_k$'s, and finally how to obtain approximations to the $s_k$'s.

LEMMA 3.2. *Equation (3.4) is equivalent to*

$$r_i = \frac{1}{i!} \sum_{i \leq k \leq n} \frac{(-1)^{i+k} s_k}{(k-i)!} \quad \text{for } 1 \leq i \leq n.$$

PROOF.    We consider (3.4) as a system of linear equations in $\mathbb{Q}(s_1, \ldots, s_n)$, with indeterminates $s_1, \ldots, s_n$. Since it is triangular with nonzero entries $k_{(k)} = k!$ on the diagonal, it has a unique solution. Thus it is sufficient to show that the quantities stated satisfy (3.4), i.e., that $s_k$ equals

$$\sum_{k \leq i \leq n} i_{(k)} \cdot \frac{1}{i!} \sum_{i \leq j \leq n} \frac{(-1)^{i+j} s_j}{(j-i)!} = \sum_{k \leq j \leq n} s_j \sum_{k \leq i \leq j} \frac{(-1)^{i+j} i!}{(i-k)! i! (j-i)!}.$$

Consider some $j$ with $k \leq j \leq n$. The coefficient of $s_j$ in the last expression equals

$$\sum_{k \leq i \leq j} \frac{(-1)^{i+j}}{(i-k)!(j-i)!} = \sum_{0 \leq l \leq j-k} \frac{(-1)^{l+k+j}}{l!(j-k-l)!}$$

$$= \frac{(-1)^{k+j}}{(j-k)!} \sum_{0 \leq l \leq j-k} (-1)^l \binom{j-k}{l} = \delta_{jk}. \qquad \square$$

COROLLARY 3.3. *In the above notation, we have*

$$\#\pi(\mathcal{C}) = \sum_{1 \leq k \leq n} \frac{(-1)^{k+1} s_k}{k!}.$$

PROOF.    By (3.3), we have

$$\#\pi(\mathcal{C}) \;=\; \sum_{1 \leq i \leq n} \sum_{i \leq k \leq n} \frac{(-1)^{i+k} s_k}{i!(k-i)!}$$

$$=\; \sum_{1 \leq k \leq n} \sum_{1 \leq i \leq k} (-1)^i \binom{k}{i} \cdot \frac{(-1)^k s_k}{k!} = \sum_{1 \leq k \leq n} \frac{(-1)^{k+1} s_k}{k!}. \qquad \square$$

A formula essentially equivalent to Corollary 3.3 in the particular case of $f = g(y) - x$ with $g \in \mathbb{F}_q[x]$ is in Birch & Swinnerton-Dyer (1959).

Suppose that we have an approximation $\sigma_k$ to $s_k$ for $1 \leq k \leq n$, so that

$$\epsilon_k = s_k - \sigma_k$$

is small in absolute value. If we set

$$\rho_i = \frac{1}{i!} \sum_{i \leq k \leq n} \frac{(-1)^{i+k} \sigma_k}{(k-i)!} \tag{3.5}$$

for $1 \leq i \leq n$, then $\rho_i$ is an approximation to $r_i$, since

$$r_i - \rho_i = \frac{1}{i!} \sum_{i \leq k \leq n} \frac{(-1)^{i+k} \epsilon_k}{(k-i)!}. \tag{3.6}$$

If $q = p$ is a prime and not too large relative to $n$, we can apply our "strip counting" method from Section 2 to the present problem.

ALGORITHM 3.4. *Projection size estimation.*
Input: *A prime $p$, $f \in \mathbb{F}_p[x,y]$ of degree $n$ and with $\mathrm{cont}_y f = 1$, and $h$ with $1 \leq h < p/2$.*
Output: *An estimate $\rho_i$ of $r_i = r_i(\mathbb{F}_p)$, as in (3.2), for $1 \leq i \leq n$.*

1. *For each $a \in A = \{0, \ldots, h-1\}$, determine*

$$\#\pi^{-1}(\{a\}) = \deg \gcd(f(a,y), y^p - y).$$

2. *For $1 \leq i \leq n$, return*

$$\rho_i = \#\{a \in A : \#\pi^{-1}(\{a\}) = i\}.$$

THEOREM 3.5. *Let $p, f, n, h$ be an input to the above algorithm and $n \geq 4$. The algorithm is deterministic and can be performed with $O(h\mathsf{M}(n) \log pn)$ operations in $\mathbb{F}_p$, and the output satisfies for all $i \leq n$*

$$|r_i - \rho_i| \leq n^{2n} h^{-1} p^{3/2} \log p.$$

PROOF. Since one gcd calculation can be done with $O(\mathsf{M}(n) \log p + \mathsf{M}(n) \log n)$ operations, the whole algorithm takes

$$O(h\mathsf{M}(n) \log(pn)) \quad \text{or} \quad O(hn \log n \, \mathrm{loglog}\, n \, \log pn)$$

operations in $\mathbb{F}_p$.

For $1 \leq k \leq n$, we consider the curve $\mathcal{S}_k \subseteq \mathbb{F}_p^{k+2}$ given by the $k+1$ polynomials

$$\begin{aligned} & f(x_0, x_1), f(x_0, x_2), \ldots, f(x_0, x_k), \\ & y \cdot \prod_{1 \leq i < j \leq k} (x_j - x_i) - 1 \in \mathbb{F}_p[x_0, \ldots, x_k, y], \end{aligned} \tag{3.7}$$

and the number

$$t_k = \#\mathcal{S}_k(A)$$

of points on $\mathcal{S}_k$ over $A$, so that

$$t_k = \sum_{k \leq i \leq n} i_{(k)} \rho_i.$$

If $\gamma_k$ is the number of absolutely irreducible components of $\mathcal{C}_k$, and we choose the approximation on $\sigma_k = \gamma_k q$, then from (3.6) and the Weil estimate for $\mathcal{C}_k$, we find an explicit estimate as (1.3) with $\lambda_i = \frac{1}{i!} \sum_{i \leq k \leq n} \frac{(-1)^{i+k} \gamma_k}{(k-i)!}$.

The curve $\mathcal{S}_k$ is isomorphic to the curve given by the first $k$ equations in (3.7) minus the diagonals, and thus the Zariski closure of the set in $\mathbb{F}_p^{k+2}$ corresponding to $S_k$, and its degree is at most $n^k$ by Bézout's Theorem.

Let $\sigma_k = p t_k / h$. By Lemma 3.1 and Theorem 2.4(i), we have

$$|s_k - \sigma_k| = p/h \cdot |h \# \mathcal{S}_k / p - \# \mathcal{S}_k(A)| \leq p/h \cdot 2.03 \, n^{2k} p^{1/2} \log p.$$

In step 2, $\rho_i$ satisfies (3.5), and we find from (3.6)

$$|r_i - \rho_i| \leq \frac{1}{i!} \sum_{i \leq k \leq n} \frac{2.03 \, n^{2k} h^{-1} p^{3/2} \log p}{(k-i)!} \leq n^{2n} h^{-1} p^{3/2} \log p. \qquad \square$$

For $n \leq 3$, we find $|r_i - \rho_i| \leq 3 n^{2n} h^{-1} p^{3/2} \log p$. As an example, suppose that $n^{2n+1} \leq p^{1/8}$, and set $h = p^{3/4}$. Then we obtain with $O\tilde{\ }(p^{3/4})$ operations in $\mathbb{F}_p$ an approximation of the $r_i$'s with error $O\tilde{\ }(p^{7/8})$.

Of course, we can also estimate $\#\pi(\mathcal{C})$ via the resultant

$$r = \mathrm{res}_y(f(x,y), y^q - y) \in \mathbb{F}_q[x],$$

whose set of roots in $\mathbb{F}_q$ equals $\pi(\mathcal{C})$. Unfortunately this does not help much as the degree of $r$ is too large.

We apply our technique to estimate the size of the image of a mapping $\mathbb{F}_p \to \mathbb{F}_p$ given by a univariate rational function.

COROLLARY 3.6. *Let $p$ be a prime, $n \geq 4$, $f = g_1/g_2 \in \mathbb{F}_p(x)$ with $g_1, g_2 \in \mathbb{F}_p[x]$ relatively prime and of degree less than $n$, $0 < h < p$, and*

$$u_i = \#\{a \in \mathbb{F}_p : \# f^{-1}(\{a\}) = i\}$$

*be the number of points in $\mathbb{F}_p$ with exactly $i$ preimages under the associated partial mapping $f : \mathbb{F}_p \to \mathbb{F}_p$, and*

$$V(f) = \sum_{1 \leq i \leq n} u_i$$

*the number of images of $f$. We can compute with $O(hM(n)\log n)$ operations
in $\mathbb{F}_p$ approximations $v_i$ and $\phi$ such that for all $i \leq n$*

$$\max\left\{|u_i - v_i|,\ n^{-1}|V(f) - \phi|\right\} \leq n^{2n}h^{-1}p^{3/2}\log p.$$

PROOF.    We apply Theorem 3.5 to the curve $\mathcal{C} = \{g_1(y) = xg_2(y)\}$. $\square$

The results of this and the previous section can be extended to counting
complete intersections over finite prime fields, by using the results of Shparlinski
& Skorobogatov (1990) on the distribution of points on such varieties instead
of Lemma 2.2.

## 4.  #$\mathcal{P}$-completeness of sparse curve counting

In this section, we show that the counting problem for sparsely represented
curves over finite fields is #$\mathcal{P}$-complete, via probabilistic Turing reductions.

We rely on hardness results proved by Quick (1986), which in turn are
based on Plaisted's (1977, 1984) work. A bonus of our approach is that we
have upper bounds matching the previously known lower bounds, so that now
some variants of Plaisted's and Quick's problems are shown to be complete for
$\mathcal{NP}$ and #$\mathcal{P}$, respectively.

Plaisted (1984), Theorem 5.1, associates to a given Boolean formula $F$ in 3-
conjunctive normal form polynomials $f_1, \ldots, f_n \in \mathbb{Z}[x]$ such that $F$ is satisfiable
if and only if $\gcd(f_1, \ldots, f_n) \neq 1$. This shows that the latter problem is $\mathcal{NP}$-
hard. Quick gives a clever parsimonious variation of this reduction, i.e., such
that the number of satisfying assignments of $F$ can be efficiently computed
from $\deg\gcd(f_1, \ldots, f_n)$ for several instances of such polynomials. This shows
that the latter problem is #$\mathcal{P}$-hard.

Here are the formal definitions—in the style of Garey & Johnson (1979)—of
our counting problems. All input numbers are represented in binary, and for
the elements of $\mathbb{Z}_p$, we use the representatives $\{0, 1, \ldots, p-1\}$. The sparse
representation of a uni- or bivariate polynomial is a list of pairs (coefficient,
exponent), and the dense representation lists all coefficients up to the degree.
A finite field $\mathbb{F}_q$ with $q = p^m$ elements, where $p$ is prime, is represented by
$(p, \psi)$, where $\psi \in \mathbb{Z}_p[x]$ is monic irreducible of degree $m$. An element $u$ of
$\mathbb{F}_q$ is represented by the usual coefficient vector $(u_0, \ldots, u_{m-1}) \in \mathbb{Z}_p^m$, with
$u \equiv \sum_{0 \leq i < m} u_i x^i \bmod \psi$.

PROBLEM 4.1. CYCLOTOMICGCD.
*Instance: $n \in \mathbb{N}$, pairwise distinct primes $p_1, \ldots, p_n \leq n^2$, $N = p_1 \cdots p_n$, and*

the sparse representations of $f_1, \ldots, f_n \in \mathbb{Z}[x]$, where $f_i$ divides $x^N - 1$ in $\mathbb{Z}[x]$ for $1 \le i \le n$.
Output: $\deg \gcd(f_1, \ldots, f_n)$.

The bound $p_i \le n^2$ is rather arbitrary.

PROBLEM 4.2. SPECIAL CYCLOTOMIC GCD.
Instance: $n, p_1, \ldots, p_n, N, f_1, \ldots, f_n$ as in CYCLOTOMIC GCD, and a prime $q$ such that $q \equiv 1 \bmod N$.
Output: $\deg \gcd(f_1, \ldots, f_n)$.

PROBLEM 4.3. COMMON ROOTS MANY.
Instance: A finite field $\mathbb{F}_q$, and the sparse representations of $f_1, \ldots, f_n \in \mathbb{F}_q[x]$.
Output: The number $\deg \gcd(f_1, \ldots, f_n, x^q - x)$ of distinct common roots of $f_1, \ldots, f_n$ in $\mathbb{F}_q$.

PROBLEM 4.4. COMMON ROOTS.
Instance: A finite field $\mathbb{F}_q$, and the sparse representations of $f, g \in \mathbb{F}_q[x]$.
Output: The number $\deg \gcd(f, g, x^q - x)$ of distinct common roots of $f$ and $g$ in $\mathbb{F}_q$.

PROBLEM 4.5. SPARSE CURVES.
Instance: A finite field $\mathbb{F}_q$, and the sparse representation of a polynomial $f \in \mathbb{F}_q[x, y]$.
Output: The number of points on the curve $\mathcal{C} = \{(a, b) \in \mathbb{F}_q^2 : f(a, b) = 0\}$.

Furthermore, we let #3SAT be the #$\mathcal{P}$-complete problem of counting the number of satisfying truth assignments for a propositional formula in 3-$CNF$ form. The following result can be obtained from Quick's (1986) work and is the basis for our completeness proofs.

FACT 4.6. #3SAT $\le$ CYCLOTOMIC GCD, via a deterministic parsimonious Turing reduction, and CYCLOTOMIC GCD is #$\mathcal{P}$-hard.

THEOREM 4.7. The problems SPECIAL CYCLOTOMIC GCD, COMMON ROOTS, COMMON ROOTS MANY, and SPARSE CURVES are #$\mathcal{P}$-complete under probabilistic polynomial-time parsimonious Turing reductions.

The proof of Theorem 4.7 makes up the remainder of this section and proceeds in three stages: first we exhibit probabilistic polynomial-time parsimonious Turing reductions

$$\textsc{SpecialCyclotomicGcd} \leq \textsc{CommonRootsMany}$$
$$\leq \textsc{CommonRoots} \leq \textsc{SparseCurves}, \qquad (4.1)$$

and then we show how to find certain prime numbers efficiently, so that Quick's reduction actually implies that $\#3\textsc{Sat} \leq \textsc{SpecialCyclotomicGcd}$. Finally, it is easy to see that $\textsc{SparseCurves} \in \#\mathcal{P}$.

For the first reduction, let $(n, p_1, \ldots, p_n, N, f_1, \ldots, f_n, q)$ be an instance of $\textsc{SpecialCyclotomicGcd}$. By assumption, all $f_i$ and $g = \gcd(f_1, \ldots, f_n) \in \mathbb{Z}[x]$ are monic. For any $u \in \mathbb{Z}[x]$, we denote by $\overline{u} \in \mathbb{F}_q[x]$ the polynomial obtained by taking each coefficient modulo $q$. The reduction maps the given instance to $(\mathbb{F}_q, \overline{f_1}, \ldots, \overline{f_n})$. We have

$$x^N - 1 = \prod_{j \mid N} \Phi_j \in \mathbb{Z}[x],$$

where $\Phi_j \in \mathbb{Z}[x]$ is the $j$th cyclotomic polynomial. Thus

$$x^N - 1 = \prod_{j \mid N} \overline{\Phi_j}$$

in $\mathbb{F}_q[x]$, and since $x^N - 1 \in \mathbb{F}_q[x]$ is squarefree, it follows that the $\overline{\Phi_j}$'s are pairwise relatively prime. For $1 \leq i \leq n$, let $A_i \subseteq \mathbb{N}$ be such that $f_i = \prod_{j \in A_i} \Phi_j$. Then

$$\overline{f_i} = \prod_{j \in A_i} \overline{\Phi_j}, \quad g = \prod_{j \in A} \Phi_j,$$

where $A = A_1 \cap \cdots \cap A_n$. Since $x^N - 1$ splits into linear factors in $\mathbb{F}_q[x]$ (see Lidl & Niederreiter (1983), Theorem 2.47), we have

$$\overline{g} = \gcd(\overline{f_1}, \ldots, \overline{f_n}) = \gcd(\overline{f_1}, \ldots, \overline{f_n}, x^q - x) = \prod_{j \in A} \overline{\Phi_j},$$

and $\deg g = \deg \overline{g}$.

For the second reduction in (4.1), we need a lemma; see Theorem 6.2 and "Note Added in Proof" of Diáz & Kaltofen (1995) for multivariate polynomials.

LEMMA 4.8. *Let $F$ be a field, $f_1, \ldots, f_n \in F[x]$ of degree at most $n$, $h = \gcd(f_1, \ldots, f_n)$, $A \subseteq F$ finite, $a_3, \ldots, a_n \in A$ uniformly chosen random elements, and $g = f_2 + \sum_{3 \leq i \leq n} a_i f_i \in F[x]$. Then $h$ divides $\gcd(f_1, g)$, and*

$$prob\{h = \gcd(f_1, g)\} \geq 1 - n/\#A.$$

PROOF. After dividing each $f_i$ by $h$, we may assume that $h = 1$, and also that $f_1 \neq 0$. Let $A_3, \ldots, A_n$ be new indeterminates over $F(x)$, $R = F[A_3, \ldots, A_n]$, $G = f_2 + \sum_{3 \leq i \leq n} A_i f_i \in R[x]$, $r = \mathrm{res}_x(f_1, G) \in R$. Then $r$ is a polynomial in $A_3, \ldots, A_n$ of degree at most $n$, and if $r(a_3, \ldots, a_n) \neq 0$, then $\gcd(f_1, g) = 1$.

Any factor $u$ of $\gcd(f_1, G)$ in $R[x]$ is in fact in $F[x]$, and therefore $u$ divides $f_1, \ldots, f_n$. It follows that $u \in F$, $\gcd(f_1, G) = 1$, and $r \neq 0$. Now Schwartz's (1980) Lemma implies the claim. $\square$

For the second reduction, let $(\mathbb{F}_q, f_1, \ldots, f_n)$ be an instance of COMMON-ROOTSMANY, and $n$ the maximal degree of $f_1, \ldots, f_n$. If $q \geq 2n$, we choose $a_3, \ldots, a_n \in \mathbb{F}_q$ at random and set

$$g = f_2 + \sum_{3 \leq i \leq n} a_i f_i \in \mathbb{F}_q[x].$$

By Lemma 4.8, the reduction to the instance $(\mathbb{F}_q, f_1, g)$ of COMMONROOTS works correctly. If $q < 2n$, we first construct a field extension of $\mathbb{F}_q$ of degree $\lceil \log_q n \rceil$ and make our random choices from this new field. This does not change the gcd to be computed. All of this can be done in random polynomial time.

The third reduction in (4.1) is given by

$$(\mathbb{F}_q, f, g) \mapsto (\mathbb{F}_q, h)$$

where $f, g \in \mathbb{F}_q[x]$ and $h = f - gy \in \mathbb{F}_q[x, y]$. We let $c = \#\mathcal{C}$ be the size of the curve $\mathcal{C} = \{(a, b) \in \mathbb{F}_q^2 : h(a, b) = 0\}$ described by $h$; this number $c$ is returned by the oracle for SPARSECURVES. The reduction returns

$$n = \lceil c/q \rceil - 1$$

if $q \nmid c$ or $g(0) \neq 0$, and

$$n = c/q$$

if $q \mid c$ and $g(0) = 0$. Let

$$n^* = \deg \gcd(f, g, x^q - x)$$

be the output required by COMMONROOTS. We prove $n^* = n$; since $g(0)$ can easily be computed and $c \leq q^2$, this will show that we have a (deterministic) polynomial-time reduction.

Let $k = \deg \gcd(g, x^q - x)$ be the number of distinct roots of $g$ in $\mathbb{F}_q$; then $0 \leq k \leq q$. For $(a, b) \in \mathbb{F}_q^2$, we have

$$
\begin{aligned}
(a, b) \in \mathcal{C} \quad &\Longleftrightarrow \quad h(a, b) = 0 \\
&\Longleftrightarrow \quad (g(a) \neq 0 \text{ and } b = f(a)/g(a)) \\
&\qquad \text{or } f(a) = g(a) = 0.
\end{aligned}
$$

Thus

$$c = (q - k) + qd^*, \quad n^* = \frac{c + k}{q} - 1.$$

Since $k \leq q$, this equals $\lceil c/q \rceil - 1$ if $q \nmid c$. If $q \mid c$, it equals $c/q - 1$ if $k = 0$ (and then $g(0) \neq 0$), and $c/q$ if $k \geq 1$ (and then $k = q$ and $g(0) = 0$). This shows $n^* = n$, and finishes the reductions in (4.1).

The following is Quick's (1986) reduction from #3SAT to CYCLOTOMIC-GCD. He uses certain polynomials $\mathrm{Poly}(F_j, Q_i) \in \mathbb{Z}[x]$ introduced by Plaisted.

ALGORITHM 4.9. *Quick's reduction.*
Input: *A Boolean formula $F = F_1 \wedge \cdots \wedge F_k$ on $n$ variables in 3-CNF form.*
Output: *The number $s$ of truth assignments that satisfy $F$.*

1. *Let $r_1, \ldots, r_n$ be the $n$ smallest prime numbers satisfying $r_i/(\log r_i)^2 \geq 1500n$. For $1 \leq i \leq n$, let $P_i = (p_{i1}, \ldots, p_{in})$ be the vector of the $n$ smallest prime numbers in the arithmetic progression $\{2 + r_i a : a \in \mathbb{N}\}$.*

2. *For $i = 1, \ldots, n$ do the following steps.*

    i. *For $j = 1, \ldots, k$ compute the sparse representation of*

    $$f_{ij} = \mathrm{Poly}(F_j, P_i) \in \mathbb{Z}[x].$$

    *[Then each $f_{ij}$ divides $x^{N_i} - 1$, where $N_i = p_{i1} \cdots p_{in}$.]*

    ii. *Call CYCLOTOMICGCD to compute $s_i = \deg \gcd(f_{i1}, \ldots, f_{ik})$.*

3. *Compute $s \in \mathbb{N}$ such that $s < r_1 \cdots r_n$ and $s \equiv s_i \bmod r_1 \cdots r_n$ for $1 \leq i \leq n$.*

The missing link in our reductions is to prove that #3SAT$\leq$ SPECIAL-CYCLOTOMICGCD, similar to Fact 4.6. For this, we have to be able to find efficiently for all $i, j \leq n$ the primes $r_i, p_{ij}$ of step 1., and furthermore primes $q_i$ such that

$$q_i \equiv 1 \bmod \prod_{1 \leq j \leq n} p_{ij}, \tag{4.2}$$

as in SPECIALCYCLOTOMICGCD. The generally valid estimates for the number of primes in arithmetic progressions are not good enough for this task. Fortunately, there are better estimates that are valid for all but a few "exceptional" moduli; see Davenport (1980), McCurley (1984). Our argument is based on the following special case of Theorem 2.1 from Alford *et al.* (1994), where we have set $A = 49/20$, $\epsilon = 1/2$, and $\delta = 2/245$ in that Theorem. We denote, as is usual, by $\pi(y; n, a)$ the number of primes up to $y$ in the arithmetic progression $a + n\mathbb{N}$, so that $\pi(y) = \pi(y; 1, 1)$.

FACT 4.10. *(Alford, Granville & Pomerance 1994) There exist positive $x_0$, $\eta \in \mathbb{R}$ and $t \in \mathbb{N}$ such that for all $x, y \in \mathbb{R}$ with $y \geq x \geq x_0$ there exists $E \subset \mathbb{N}$ with $\#E < t$ and $e \geq \log x$ for all $e \in E$, and such that*

$$\pi(y; n, a) \geq \frac{\pi(y)}{2\phi(n)}$$

*whenever $\gcd(a, n) = 1$, $1 \leq n \leq \min\{x^{2/5}, yx^{-3/5}\}$, and $n$ is not divisible by any $e \in E$. Furthermore, there exists $e_0$ such that $e \geq x^\eta$ for all $e \in E$ with $e \neq e_0$.*

We now consider the following algorithm, which takes as inputs $n$ and $c \geq 1$. It also uses $x_0$, $\eta$, and $t$ as above.

1. Set $B = 3cn \log^2 n$ and determine the first $n + 1$ primes $r_0, \ldots, r_n$ that are at least $B/2$.

2. For $i = 0, \ldots, n$, determine the first $nt$ primes $p_{i,1}, \ldots, p_{i,nt}$ in the arithmetic progression $2 + r_i \mathbb{N}$, by consecutively testing its members for primality. If a member greater than $x = \max\{B^{1/\eta}, x_0\}$ has to be tested, mark $i$ as "exceptional" and abandon that $i$. [At most one number $i$ will be so marked.] Renumber the $r_i$'s so that $r_1, \ldots, r_n$ are not marked "exceptional".

3. Set $y = x^{5n/2}$ and $m = \lceil 5n \log x \cdot \log(2/\gamma) \rceil$. For $i = 1, \ldots, n$, do the following.

   i. For $1 \leq k \leq t$, set $n_{ik} = \prod_{(k-1)n < j \leq kn} p_{ij}$.

   ii. For $1 \leq k \leq t$, choose $m$ integers $t_{ik\ell}$ in $\{1, \ldots, \lfloor y/n_{ik} \rfloor\}$ uniformly at random, for $1 \leq \ell \leq m$.

   iii. For $1 \leq k \leq t$ and $\ell = 1, \ldots, m$, test $1 + t_{ik\ell} \cdot n_{ik}$ for primality. If some prime $q_i$ is found, then include this prime in the output, else return "failure".

For the primality test in the last step, we may use any of the usual probabilistic tests with an additional input $\gamma > 0$: it takes time polynomial in the input size and $\log \gamma^{-1}$, returns the correct answer if the input is prime, and for a composite input, it returns the correct answer with probability at least $1 - \gamma/2tn^2$. In Fact 4.10, we may assume that $\eta \leq 2/7$. We set

$$N = \max\{2 \cdot 10^{34}, 2/5\eta, 100t^2, c^{10}\}.$$

THEOREM 4.11. *The above algorithm uses $(n \log \gamma^{-1})^{O(1)}$ bit operations and, if $n \geq N$, it returns with probability at least $1 - \gamma$ values which have the following properties for $1 \leq i \leq n$:*

(i) *a prime $r_i$ such that $cn \log^2 r_i \leq B/2 \leq r_i \leq B$ and $r_j \neq r_i$ for all $j \neq i$,*

(ii) *distinct primes $p_{i1}, \ldots, p_{in}$ such that $p_{ij} \leq \max\{B^{1/\eta}, x_0\}$ and $p_{ij} \equiv 2 \bmod r_i$ for all $j$,*

(iii) *a prime $q_i$ satisfying (4.2).*

PROOF.    The time bound is clear. We will show that (i) and (ii) always hold, and that (iii) is probably true.

For (i), we have by Rosser & Schoenfeld (1962, 3.8) that

$$\pi(B) - \pi(B/2) \geq \frac{3B}{10 \log(B/2)} = \frac{9n \log^2 n}{10} \cdot \frac{c}{\log c + \log(\frac{3}{2}n \log^2 n)}.$$

Since $c \geq 1$ and $n \geq 11$, for any $A \geq 1$ we have

$$\log(\frac{3}{2}n \log^2 n) \geq 1, \qquad \frac{c}{\log c + A} \geq \frac{1}{A},$$
$$\frac{9}{10}n(\log n)^{1/4} \geq n + 1, \qquad (\log n)^{7/4} \geq \log(\frac{3}{2}n \log^2 n).$$

This implies that

$$\pi(B) - \pi(B/2) \geq \frac{9n \log^2 n}{10} \cdot \frac{1}{\log(\frac{3}{2}n \log^2 n)} \geq n + 1,$$

so that $r_n \leq B$. The assumption that $n \geq N$ implies that

$$
\begin{aligned}
n^{1/10} &\geq c, \\
n^{\sqrt{3/2}-11/10} &\geq 3 \log^2 n, \\
n^{\sqrt{3/2}-1} &\geq 3c \log^2 n, \\
\frac{3}{2} \log^2 n &\geq \log^2(3cn \log^2 n) = \log^2 B,
\end{aligned}
$$

and for all $i \leq n$

$$r_i \geq r_0 \geq B/2 = \frac{3}{2}cn \log^2 n \geq cn \log^2 B \geq cn \log^2 r_n \geq cn \log^2 r_i.$$

For (ii), we first note that $r_i \leq x^\eta$ for each $i \leq n$. The assumptions that $\eta \leq 2/7$ and $n \geq N$ imply that

$$
\begin{aligned}
(2 - 5\eta)/2\eta &\geq 1, \\
\eta B^{(2-5\eta)/2\eta} &\geq \eta n^{(2-5\eta)/2\eta} \geq \frac{2}{5}, \\
\eta B^{1/\eta} &\geq \frac{2}{5} B^{5/2}.
\end{aligned}
$$

Since $\pi(x) \geq x/\log x$, Fact 4.10 says that for all $i$ with at most one exception (namely, when possibly $r_i = e_0$) we have

$$
\begin{aligned}
\pi(x; r_i, 2) &\geq \frac{\pi(x)}{2\phi(r_i)} \geq \frac{B^{1/\eta}}{2\log(B^{1/\eta})B} \\
&= \frac{\eta B^{1/\eta - 1}}{2\log B} \geq \frac{\frac{2}{5} B^{3/2}}{2\log B} = \frac{(3cn\log^2 n)^{3/2}}{5\log(cn\log^2 n)}.
\end{aligned}
$$

We have $c^{3/2} \geq \log c$, $n \geq \log^2 n$, and

$$
3^{3/2} n^{1/2} \log^2 n > n^{1/2} \geq 10t,
$$

so that

$$
\begin{aligned}
\frac{(3cn\log^2 n)^{3/2}}{5\log(cn\log^2 n)} &\geq \frac{3^{3/2} c^{3/2} n^{3/2} \log^3 n}{5(\log c + \log(n^2))} \\
\geq \frac{3^{3/2} c^{3/2} n^{3/2} \log^3 n}{5\log c \cdot \log(n^2)} &\geq tn \cdot \frac{3^{3/2} n^{1/2} \log^3 n}{10t\log n} > tn.
\end{aligned}
$$

This shows that for all but at most one $i$ we will find $tn$ primes $p_{ij} \leq x$, and that indeed at most one $i$ will be marked "exceptional" in step 2.

For (iii), fix some $i$ with $1 \leq i \leq n$. Since $n_{i1}, \ldots, n_{it}$ are pairwise relatively prime, each $e \in E$ divides at most one of them, and some $n_{ij}$ is not a multiple of any $e \in E$; denote this value of $j$ by $j_0$, and $n = n_{ij_0}$. We show that step 3.iii for $j = j_0$ is likely to return a prime satisfying (iii). We have

$$
\pi(y; n, 1) \geq \frac{\pi(y)}{2\phi(n)} \geq \frac{y}{2\log y \cdot n}.
$$

Therefore, for $q = 1 + td$ with $t \in \{1, \ldots, \lfloor y/n \rfloor\}$ random, we have

$$\text{prob}(q \text{ prime}) \geq \frac{\pi(y; n, 1)}{\lfloor y/n \rfloor} \geq \frac{y}{2 \log y \cdot d \cdot y/n} = \frac{1}{2 \log y} = \frac{1}{5n \log x}.$$

Therefore, the probability that none of the random choices gives a prime number is at most

$$\left(1 - \frac{1}{5n \log x}\right)^m \leq \left(1 - \frac{1}{5n \log x}\right)^{5n \log x \cdot \log(2/\gamma)} \leq e^{-\log(2/\gamma)} = \frac{\gamma}{2}.$$

Furthermore, the probability that all primality tests answer correctly is at least

$$\left(1 - \frac{\gamma}{2tn^2}\right)^{tn^2} \geq 1 - \frac{\gamma}{2},$$

so that step 3.iii returns a prime number $q_i$ with probability at least $(1 - \frac{\gamma}{2})^2 \geq 1 - \gamma$. □

We can now prove the main result of this Section.

PROOF of Theorem 4.7. Using Theorem 4.11, we can implement Quick's reduction so that it actually yields $\#3\text{SAT} \leq \text{SPECIAL CYCLOTOMIC GCD}$. By the $\#\mathcal{P}$-completeness of $\#3\text{SAT}$ and (4.1), it is sufficient to see that SPARSE CURVES $\in \#\mathcal{P}$. We consider a non-deterministic Turing machine which on input $(\mathbb{F}_q, f)$ generates all pairs $(a, b) \in \mathbb{F}_q^2$ and checks for each whether $(a, b) \in \mathcal{C} = \{f = 0\}$. If so, it accepts, and otherwise it rejects. Thus the number of accepting computations is $\#\mathcal{C}$. Each check can be done in polynomial time. □

# 5. Reduction to absolutely irreducible curves

In this section, we show that the computation of the size of a plane curve can be reduced in random polynomial time to the same question about absolutely irreducible curves. This is the case to which Weil's Theorem applies.

So now we are given $f \in \mathbb{F}_q[x, y]$ of degree $n$, and want to compute $\#\mathcal{C}$ for $\mathcal{C} = \{f = 0\} \subseteq \mathbb{F}_p^2$. We factor $f$ as

$$f = f_1 \cdots f_\tau,$$

with $f_1, \ldots, f_\tau \in \mathbb{F}_q[x, y]$ irreducible.

There are several algorithms in the literature for this factorization: Chistov & Grigoryev (1982), Lenstra (1985), and von zur Gathen & Kaltofen (1985).

The latter paper gives $O^\tilde{}(n^7(n^5 + \log q)\log^2 q)$ bit operations. These algorithms are probabilistic of the Las Vegas type, i.e., they never return an incorrect answer, but they may fail, with controllably small probability. Shparlinski (1992a), Theorem 1.7, gives a deterministic method whose cost is $O(n^{3.7}\log q)$ for *almost all* input polynomials.

We will assume from now on, without loss of generality, that $f$ is squarefree.

Next we determine for each $f_i$ whether it is *absolutely irreducible*, i.e., irreducible over an algebraic closure of $\mathbb{F}_q$. Kaltofen's (1985) algorithm takes $O(n^9)$ operations in $\mathbb{F}_q$.

We order the irreducible factors of $f$ so that $f_1, \ldots, f_\sigma$ are absolutely irreducible and $f_{\sigma+1}, \ldots, f_\tau$ are not, for some $\sigma \leq \tau$. For $1 \leq i, j \leq \tau$, we set

$$
\begin{aligned}
U_i &= \{f_i = 0\} \subseteq \mathbb{F}_q^2, & u_i &= \#U_i, \\
V_{ij} &= \{f_i = f_j = 0\} \subseteq \mathbb{F}_q^2, & v_i &= \# \bigcup_{k \neq i} V_{ik}.
\end{aligned}
$$

Since $\mathcal{C} = \bigcup_{1 \leq i \leq \tau} U_i$, we have

$$
\#\mathcal{C} = \sum_{1 \leq i \leq \tau} (u_i - v_i) + \# \bigcup_{1 \leq i < j \leq \tau} V_{ij}.
$$

We now show how to compute all these quantities quickly, except for the $u_i$ with $i \leq \sigma$.

LEMMA 5.1. *Let $F$ be a field, and $f, g \in F[x, y]$ have total degree at most $n$. Then the resultant*

$$
r = res_y(f, g) \in F[x]
$$

*can be computed with $O(M(n^3)\log n)$ operations in $F$.*

PROOF.    It is well-known that $r$ can be calculated by a fast continued-fraction algorithm in $F(x)[y]$ and using the subresultant description of $r$ with $O(M(n)\log n)$ operations in $F(x)$; see, e.g., von zur Gathen (1991), steps 4, 5, 6 of the algorithm in Section 2. By the subresultant theory, the degree in $x$ of each intermediate result is at most $n^2$, so that the total cost is $O(M(n)(n^2)\log n)$ operations in $F$. In fact, using Lemma 2.2 from von zur Gathen & Shoup (1992), this can be done with $O(M(n^3)\log n)$ operations. $\square$

LEMMA 5.2. *Let $f, g \in \mathbb{F}_q[x, y]$ have total degree $m, n$, respectively, and assume that $m \leq n$.*

(i) If $\gcd(f, g) = 1$, then

$$V = \{(a, b) \in \mathbb{F}_q^2 : f(a, b) = g(a, b) = 0\}$$

can be computed probabilistically with $O((n^4 + n^2 \log q) \cdot \log^2 n \, \mathrm{loglog} \, n)$ operations in $\mathbb{F}_q$, and

$$\#V \leq mn.$$

(ii) If $f$ is irreducible and not absolutely irreducible, then

$$U = \{(a, b) \in \mathbb{F}_q^2 : f(a, b) = 0\}$$

can be computed probabilistically with $\tilde{O}(n^{11}(n^4 + \log q) \log^2 q)$ operations in $\mathbb{F}_q$, and

$$\#U \leq n^2/4.$$

PROOF.     (i) The classical method for finding $V$ is to compute the resultant

$$r = \mathrm{res}_y(f, g) \in \mathbb{F}_q[x],$$

find all roots $a_1, \ldots, a_k \in \mathbb{F}_q$ of $r$, and then all roots $b_{ij}$ in $\mathbb{F}_q$ of

$$h_i = \gcd(f(a_i, y), g(a_i, y), y^q - y) \in \mathbb{F}_q[y],$$

for $1 \leq i \leq k$. Then $V$ is the set of all these $(a_i, b_{ij})$.

By Lemma 5.1, $r$ can be computed with $O(M(n^3) \log n)$ operations in $\mathbb{F}_q$. Since $\deg r \leq n^2$, we can compute $a_1, \ldots, a_k$ (probabilistically) with $O((n^4 + n^2 \log q) \cdot \log^2 n \, \mathrm{loglog} \, n)$ operations in $\mathbb{F}_q$ (von zur Gathen & Shoup 1992). Now fix some $i \leq k$. Then $y^q \bmod f(a_i, y)$ can be calculated with $O(M(n) \log(dq))$ operations in $\mathbb{F}_q$, and then $h_i$ with $\tilde{O}(n)$ operations. All roots of $h_i$ can be found with $\tilde{O}(n_i^2 + n_i \log q)$ operations in $\mathbb{F}_q$, where $n_i = \deg h_i$. Since $\sum_{1 \leq i \leq k} n_i \leq mn \leq n^2$ by Bézout's Theorem, the total time is $\tilde{O}(n^4 + n^2 \log q)$, and also $\#V \leq mn$.

(ii) The assumption implies that for some $e \leq n$, $f$ has a nontrivial factorization $f_1 \cdots f_r$ with $f_1, \ldots, f_r \in \mathbb{F}_{q^e}[x, y]$ irreducible and $r \geq 2$. We first find an irreducible polynomial $h \in \mathbb{F}_q[x]$ of degree $e$, so that $\mathbb{F}_{q^e} = \mathbb{F}_q[x]/(h)$, and then factor $f$ into two factors $f = h_1 h_2$ over $\mathbb{F}_{q^e}$, with

$$\tilde{O}(n^7(n^5 + \log q^e) \log^2(q^e))$$

operations in $\mathbb{F}_{q^e}$, or

$$\tilde{O}(n^{11}(n^4 + \log q) \log^2 q)$$

operations in $\mathbb{F}_q$. Then we apply (i) to $h_1$ and $h_2$, which yields

$$V = \{(a, b) \in \mathbb{F}_{q^e}^2 : h_1(a, b) = h_2(a, b) = 0\}.$$

Then $U = V \cap \mathbb{F}_q^2$, since the Galois group of $\mathbb{F}_{q^e}$ over $\mathbb{F}_q$ operates transitively on $\{f_1, \ldots, f_r\}$, and

$$\#U \leq \#V \leq \deg h_1 \cdot \deg h_2 \leq n^2/4,$$

by Bézout's Theorem (or Lemma 2.1). $\square$

THEOREM 5.3. *Let* $f \in \mathbb{F}_q[x, y]$ *have degree* $n$, *and* $\mathcal{C} = \{f = 0\}$.

(i) *We can compute probabilistically the number of irreducible (over* $\mathbb{F}_q$*) components and the number of absolutely irreducible components of* $\mathcal{C}$ *with* $O\tilde{\ }(n^{11}(n^4 + \log q) \log^2 q)$ *operations in* $\mathbb{F}_q$.

(ii) *Suppose that we know* $\#\{g = 0\}$ *for each absolutely irreducible factor* $g \in \overline{\mathbb{F}}_q[x, y]$ *of* $f$. *Then we can determine* $\#\{f = 0\}$ *probabilistically with the same number of operations.*

PROOF. (i) has been proven above. For (ii), we use Lemma 5.2 to calculate all $U_i$ and $u_i$ with $i > \sigma$, and all $V_{ij}$ and $v_i$ as above. $\square$

# 6. The number of points in extensions

The following result shows how to compute $N_k(\overline{\mathcal{C}})$ quickly for curves given by an equation of "small" degree over a "small" field.

The basic idea is rather simple and probably has been known as folklore. However, here we show that it can be implemented in an efficient way.

THEOREM 6.1. *Let* $\mathcal{C}$ *be a smooth projective absolutely irreducible plane curve over* $\mathbb{F}_q$ *of degree* $n$ *and* $k \in \mathbb{N}$. *Then* $N_k(\overline{\mathcal{C}})$ *can be calculated with* $O\tilde{\ }(q^{2n^2})$ *operations in* $\mathbb{F}_q$, *plus* $O\tilde{\ }(nk \log q)$ *bit operations.*

PROOF. Let $g \leq n^2/2$ be the genus of $\mathcal{C}$. Each Frobenius root $\vartheta$ in (1.1) satisfies a polynomial equation

$$a = \sum_{0 \leq j \leq 2g} a_j x^j \in \mathbb{Q}[x] \quad \text{with } a_{2g} = 1 \text{ and } a(\vartheta) = 0.$$

Since $|\vartheta| = q^{1/2}$, we have

$$|a_j| \leq \binom{n^2}{j} q^{j/2}$$

for all $j$. The integers

$$u_l = N_l(\mathcal{C}) - q^l - 1 = \sum_{1 \leq i \leq g} (\vartheta_i^l + \overline{\vartheta}_i^l)$$

satisfy the linear recurrence relation

$$\sum_{0 \leq j \leq 2g} a_j u_{l+j} = 0$$

for all $l \geq 0$. We first calculate $v_1 = (u_1, \ldots, u_{2n^2})$ by the brute force method (including the points "at infinity") with

$$O\tilde{\ }(\sum_{1 \leq j \leq 2n^2} nq^j) = O\tilde{\ }(q^{2n^2})$$

operations in $\mathbb{F}_q$. If $k \leq 2n^2$, we are done. Otherwise, we calculate the recurrence coefficients $a_1, \ldots, a_{2g}$ with $O(M(n^2) \log n)$ operations in $\mathbb{Q}$ (von zur Gathen & Shoup (1992), Lemma 10.1), in particular we compute the genus $g$. Using repeated squaring, we compute $b = \sum_{0 \leq j < 2g} b_j x^j \in \mathbb{Q}[x]$ such that

$$b \equiv x^{k-1} \bmod a,$$

with $O\tilde{\ }(n \log k)$ operations in $\mathbb{Q}$. Then

$$\vartheta^k = \sum_{1 \leq j \leq 2g} b_{j-1} \vartheta^j.$$

Finally, we compute

$$u_k = \sum_{1 \leq j \leq 2g} b_{j-1} u_j$$

Since $u_j \leq q^{2j}$ for all $j$, all rational numbers occurring in this computation have binary length $O(k \log q)$, and the last part of the algorithm can be done with $O\tilde{\ }(nk \log q)$ bit operations. $\square$

This method is better than the "brute force" method whenever $n^2 \leq k/2$. If $n^2 \leq 0.5 \log_q k$, it uses quasi-linear time $O\tilde{\ }(k \log q)$.

OPEN QUESTION 6.2. *Can we extract some nontrivial information about $N_k(\overline{\mathcal{C}})$ from the first $\ell < 2g$ values $N_j(\mathcal{C})$ for $1 \leq j \leq \ell$?*

OPEN QUESTION 6.3. *Is it possible to generalize Theorem 6.1 to the case where $n$ and $q$ are small but the curve is given by an equation over $\mathbb{F}_{q^k}$ rather than over $\mathbb{F}_q$?*

# 7. Probabilistic approximation of the size of a curve

Ma & von zur Gathen (1995) have previously given a probabilistic algorithm to estimate the size of the image of a rational function. We now give a similar algorithm for the more general problem of estimating the number $\#\mathcal{C}$ of points on a curve $\mathcal{C} = \{f = 0\}$, where $f \in \mathbb{F}_q[x, y]$ of degree $n$ is given.

ALGORITHM 7.1. *Approximation Scheme.*
Input: $f \in \mathbb{F}_q[x, y]$ *and* $t \in \mathbb{N}$.
Output: *An estimate* $E$ *of* $\#\{f = 0\}$.

1. *Choose* $t$ *random independent uniformly distributed elements* $a_1, \ldots, a_t$ *in* $\mathbb{F}_q$.

2. *For* $j = 1, \ldots, t$, *compute the number* $m_j = \deg \gcd(f(x, a_j), x^q - x)$ *of* $u \in \mathbb{F}_q$ *with* $f(u, a_j) = 0$.

3. *Return* $E = q(m_1 + \ldots + m_t)/t$.

THEOREM 7.2. *Let* $\mathcal{C}$ *be a plane curve given by* $f \in \mathbb{F}_q[x, y]$ *of degree* $n$ *without vertical lines. Then Algorithm Approximation Scheme uses* $O(tM(n)\log(nq))$ *or* $O\tilde{\ }(tn \log q)$ *operations in* $\mathbb{F}_q$, *and for any* $\delta > 0$ *we have*

$$\Pr\left\{ |\#\mathcal{C} - E| \le \left( 2n(n+1)\log(2n/\delta)qt^{-1}\#\mathcal{C} \right)^{1/2} \right\} \ge 1 - \delta.$$

PROOF. Using $r_i$ and $R_i$ from (3.2), we have

$$E = \frac{q}{t} \sum_{1 \le i \le n} i \sum_{a_j \in R_i} 1.$$

Then writing

$$c = (4\log(2n/\delta)qt^{-1})^{1/2} \quad \text{and} \quad \epsilon_i = cr_i^{-1/2} \text{ for } 1 \le i \le n,$$

we get from the general result in Karp *et al.* (1989)

$$\Pr\left\{ |r_i - \frac{q}{t} \sum_{\substack{a_j \in R_i \\ 1 \le j \le t}} 1| \ge \epsilon_i r_i \right\} \le \delta/n \quad \text{for } 1 \le i \le n.$$

This inequality and $\#\mathcal{C} = \sum_{1 \le i \le n} ir_i$ imply that

$$\Pr\{ |\#\mathcal{C} - E| \ge \sum_{1 \le i \le n} i\epsilon_i r_i \} \le \delta.$$

Furthermore, we have

$$
\begin{aligned}
\sum_{1\leq i\leq n} i\epsilon_i r_i \;=\; c\sum_{1\leq i\leq n} i\sqrt{r_i} \;&\leq\; c\Big(\sum_{1\leq i\leq n} i\Big)^{1/2}\Big(\sum_{1\leq i\leq n} ir_i\Big)^{1/2}\\
&=\; c(n(n+1)/2)^{1/2}\#\mathcal{C}^{1/2},
\end{aligned}
$$

which implies our claim. $\square$

Using the trivial bound $\#\mathcal{C} \leq nq$, we can rewrite Theorem 7.2 in the following form.

COROLLARY 7.3. *Let $\mathcal{C}$ be a plane curve given by an equation of degree $n$ over $\mathbb{F}_q$ and without vertical lines. Then the algorithm uses $O\tilde{\ }(tn\log q)$ operations in $\mathbb{F}_q$, and for any $\delta > 0$ we have*

$$
\Pr\{|\#\mathcal{C} - E| \leq nq[2(n+1)\log(2n/\delta)t^{-1}]^{1/2}\} \geq 1 - \delta.
$$

For fixed $\delta > 0$, the error term is $O\tilde{\ }(n^{3/2}qt^{-1/2})$.

We have three methods for deriving estimates for $\#\mathcal{C}$: the Weil estimate (1.2), which requires the number of absolutely irreducible components of $\mathcal{C}$, the brute force method of Lemma 2.5 (with $m = k = 1$, $A = \mathbb{F}_q$), and the probabilistic method of Corollary 7.3. The following are the parameters for these three algorithms, for any $\alpha > 0$:

|       | Weil          | Lemma 2.5 | probabilistic      |
|-------|---------------|-----------|--------------------|
| error | $n^2 q^{1/2}$ | $0$       | $q^{\alpha}$       |
| time  | $0$           | $nq$      | $n^4 q^{2-2\alpha}$ |

all in the $O\tilde{\ }$ sense.

Our probabilistic method is competitive when $n$ is at least a constant power of $q$. The novelty in the method is that we allow a trade-off between accuracy and computing effort. As a concrete example, let us consider the case when $\mathcal{C}$ is absolutely irreducible and $n$ is close to $q^{1/4}$. Then we have

|       |      |           | probabilistic |                 |
|-------|------|-----------|---------------|-----------------|
|       | Weil | Lemma 2.5 | general       | $\alpha = 15/16$ |
| error | $q$  | $0$       | $q^{\alpha}$  | $q^{15/16}$     |
| time  | $0$  | $q^{5/4}$ | $q^{3-2\alpha}$ | $q^{9/8}$     |

again in the $O\~$ sense. Thus the last algorithm gives a better result for approximations with error between $q^{7/8}$ and $q$.

For general plane curves of large degree $n$, when the required factorization procedure may preclude the application of Weil's estimate in practice, our probabilistic estimate is better than the brute force method whenever one can tolerate an error $q^\alpha$ with $q^{2\alpha-1}$ sufficiently greater than $n^3$.

For absolutely irreducible curves, the Weil bound (1.2) provides the following improvement of Corollary 7.3.

COROLLARY 7.4. *Let* $\mathcal{C}$ *be an absolutely irreducible plane curve given by an equation of degree* $n$ *over* $\mathbb{F}_q$ *and without vertical lines. Then the algorithm uses* $O\~(tn \log q)$ *operations in* $\mathbb{F}_q$, *and for any* $\delta > 0$ *we have*

$$\Pr\{|\#\mathcal{C} - E| \le [2(n+1)\log(2n/\delta)q(q+n^2q^{1/2})t^{-1}]^{1/2}\} \ge 1 - \delta.$$

Our algorithms are in the spirit of the $(\epsilon, \delta)$-approximation schemes of Karp *et al.* (1989), Grigoryev & Karpinski (1991), Karpinski & Luby (1993). However, they are not uniform in terms of $\epsilon$ and $\delta$, because the curve size occurs as $\#\mathcal{C}^{1/2}$ in the estimate on the right hand side rather than linearly. However, if $\mathcal{C}$ contain at least one absolutely irreducible component and $q$ is large enough such a result can be obtained.

COROLLARY 7.5. *Let* $\mathcal{C}$ *be a plane curve given by an equation of degree* $n$ *over* $\mathbb{F}_q$, *containing at least one absolutely irreducible component and without vertical lines. Assume that* $q \ge 4n^4$. *Then for any positive* $\epsilon$ *and* $\delta$ *and*

$$t = \lceil 4\epsilon^{-2}n(n+1)\log(2n/\delta) \rceil$$

*the algorithm uses* $O\~(\epsilon^{-2}n^3 \log(2n/\delta))$ *operations in* $\mathbb{F}_q$, *and*

$$\Pr\{|\#\mathcal{C} - E| \le \epsilon\#\mathcal{C}.$$

PROOF. We have
$$\#\mathcal{C} \ge q - n^2q^{1/2} \ge q/2,$$
$$\left(2n(n+1)\log(2n/\delta)qt^{-1}\#\mathcal{C}\right)^{1/2} \le \epsilon(q\#\mathcal{C}/2)^{1/2} \le \epsilon\#\mathcal{C}. \qquad \square$$

Now we give a similar algorithm to count the size of the projection.

ALGORITHM 7.6. *Projection Approximation.*
Input: $f \in \mathbb{F}_q[x,y]$ *and* $t \in \mathbb{N}$.
Output: *An estimate* $E$ *of* $\#\pi\{f = 0\}$.

1. *Choose $t$ random independent uniformly distributed elements $a_1, \ldots, a_t$ $\in \mathbb{F}_q$.*

2. *For $j = 1, \ldots, t$, set $m_j = \min\{1, \deg \gcd(f(x, a_j), x^q - x)\}$*

3. *Return $E = q(m_1 + \ldots + m_t)/t$.*

THEOREM 7.7. *Let $\mathcal{C}$ be a plane curve given by $f \in \mathbb{F}_q[x, y]$ of degree $n$ and without vertical lines. Then Algorithm Projection Approximation uses $O(tM(n)\log(nq))$ or $O\tilde{\ }(tn\log q)$ operations in $\mathbb{F}_q$, and for any $\delta > 0$ we have*

$$\Pr\left\{ |\#\pi(\mathcal{C}) - E| \leq 2\Big(\log(2/\delta)qt^{-1}\#\pi(\mathcal{C})\Big)^{1/2} \right\} \geq 1 - \delta.$$

PROOF.    This follows from the general result in Karp *et al.* (1989). $\square$

Certainly one can use the bound $\#\pi(\mathcal{C}) \geq \#\mathcal{C}/n$ and obtain an $(\epsilon, \delta)$-approximation scheme under similar conditions as in Corollary 7.5.

OPEN QUESTION 7.8. *Obtain general uniform $(\epsilon, \delta)$-approximation algorithms for the problems considered in this section.*

In a subsequent paper (von zur Gathen & Shparlinski 1994), we just take $a \in \mathbb{F}_q$ at random, set $a_i = a + i$ for $1 \leq i \leq t$, and show that these dependent random variables yield a reasonable approximation of $\#\mathcal{C}$.

# 8. Sparse Artin-Schreier hypersurfaces

In this section, we present a method to determine whether an Artin-Schreier hypersurface given by a sparse polynomial has a rational point. We consider a polynomial $f \in \mathbb{F}_{q^k}[x_1, \ldots, x_m]$ that is the sum of at most $t$ monomials, i.e., $f$ is $t$-*sparse*, and the corresponding Artin-Schreier hypersurface

$$f(x_1, \ldots, x_m) = y^q - y. \tag{8.1}$$

Of particular interest is the case of an Artin–Schreier curve, where $m = 1$. Let

$$\mathrm{T}(x) = \sum_{0 \leq i < k} x^{q^i} \in \mathbb{F}_{q^n}[x]$$

denote the trace polynomial over $\mathbb{F}_q$. We write $q = p^r$, with $p$ prime, and first present a deterministic algorithm to determine the set

$$\{(\mathrm{T} \circ f)(u) : u \in \mathbb{F}_{q^k}^m\} \subseteq \mathbb{F}_q$$

of values which the trace of $f$ takes.

Our algorithm runs in time $(kt + 1)^{O(mpr)}$ instead of the naive $\tilde{O}(tq^{km})$. Thus, for fields of fixed characteristic the running time can be estimated as $q^{O(m \log kt)}$. A trivial lower bound for any such algorithm is the size of the output, which may be about $q$.

For $f \in \mathbb{F}_q[x_1, \ldots, x_m]$ and $V \subseteq \mathbb{F}_q^m$, we write $f(V) = \{f(v) : v \in V\}$ for the set of values of $f$ on $V$.

LEMMA 8.1. *Let $\theta$ be a primitive root of $\mathbb{F}_q$, and*

$$U = \{0\} \cup \{\theta^e \in \mathbb{F}_q : 0 \le e < s\} \subseteq \mathbb{F}_q. \tag{8.2}$$

*Then for any $s$-sparse $f \in \mathbb{F}_q[x_1, \ldots, x_m]$ we have*

$$f(\mathbb{F}_q^m) = \{0\} \iff f(U^m) = \{0\}.$$

PROOF.    It is sufficient to prove "$\Longleftarrow$" by induction on $m$, starting with $m = 1$. We write $f = \sum_{1 \le i \le s} a_i x^{e_i}$, with all $a_i \in \mathbb{F}_q$ and $e_i \in \mathbb{N}$. For $d, e \in \mathbb{N}$ with $d, e \ge 1$, we have

$$(\forall a \in \mathbb{F}_q \quad a^d = a^e) \iff d \equiv e \bmod q - 1.$$

By replacing each $e_i > 0$ by its representative $d_i$ modulo $q - 1$ with $1 \le d_i < q$ and adding coefficients of equal exponents, we obtain $g = \sum_{1 \le i \le t} b_i x^{d_i} \in \mathbb{F}_q[x]$, with $t \le s$, $b_1, \ldots, b_t \in \mathbb{F}_q$, $0 \le d_1 < \cdots < d_t < q$, and $f(a) = g(a)$ for all $a \in \mathbb{F}_q$. By assumption, we have

$$g(u) = 0 \text{ for all } u \in U. \tag{8.3}$$

In particular, the constant coefficient of $g$ is zero. Since $\deg g < q$, the elements $\theta^{d_i}$ for $1 \le i \le t$ are pairwise distinct, and (8.3) corresponds to a Vandermonde system of linear equations. It follows that $b_i = 0$ for all $i$, and hence $f(a) = 0$ for all $a \in \mathbb{F}_q$.

The induction step is left to the reader. $\square$

THEOREM 8.2. *Let $m, k, t \ge 1$, $q = p^r$, $f \in \mathbb{F}_{q^k}[x_1, \ldots, x_m]$ be $t$-sparse, $\theta \in \mathbb{F}_{q^k}$ primitive, $s = (kt + 1)^{(p-1)r} + 1$, and $U \subseteq \mathbb{F}_{q^k}$ as in (8.2). Then*

$$(T \circ f)(\mathbb{F}_{q^k}^m) = (T \circ f)(U^m).$$

PROOF.    For any $a \in \mathbb{F}_q$, there exists $u \in \mathbb{F}_{q^k}^m$ with $(\mathrm{T} \circ f)(u) = a$ if and only if the polynomial

$$g_a = (\mathrm{T} \circ f - a)^{q-1} - 1 \in \mathbb{F}_{q^k}[x_1, \ldots, x_m]$$

assumes a nonzero value on $\mathbb{F}_{q^k}^m$.

In general, the $e$th power of an $i$-sparse polynomial is $i^e$-sparse, and if $e$ is a power of the field characteristic $p$, then this $e$th power is $i$-sparse. Furthermore, the product of an $i$-sparse and a $j$-sparse polynomial is $ij$-sparse. It follows that $(\mathrm{T} \circ f) - a$ is $(kt + 1)$-sparse. Taking into account that $q - 1 = (p - 1) \cdot (p^{r-1} + \cdots + p + 1)$, we find that the polynomial $g_a$ is $s$-sparse. Using Lemma 8.1, we find for any $a \in \mathbb{F}_q$ that

$$a \in (\mathrm{T} \circ f)(\mathbb{F}_{q^k}^m) \iff g_a(\mathbb{F}_{q^k}^m) \neq \{0\}$$

$$\iff g_a(U^m) \neq \{0\} \iff a \in (\mathrm{T} \circ f)(U^m). \qquad \square$$

COROLLARY 8.3. Let $m, k, t \geq 1$, $q = p^r$, $f \in \mathbb{F}_{q^k}[x_1, \ldots, x_m]$ be $t$-sparse. Then the image of $\mathrm{T} \circ f : \mathbb{F}_{q^k}^m \to \mathbb{F}_q$ can be calculated with $(kt + 1)^{O(mpr)}$ evaluations of $\mathrm{T} \circ f$.

PROOF.    Using the algorithms of Shoup (1992) or Shparlinski (1990) (see also Shparlinski 1992a), we can construct in time $(pkr)^{O(1)}$ a set $M \subseteq \mathbb{F}_{q^k}$ with cardinality $(pkr)^{O(1)}$ containing a primitive root of $\mathbb{F}_{q^k}$. Setting

$$U_\mu = \{0\} \cup \{\mu^e \in \mathbb{F}_{q^k} : 0 \leq e < s\} \subseteq \mathbb{F}_{q^k}$$

for $\mu \in M$, we have from Theorem 8.2 that

$$(\mathrm{T} \circ f)(\mathbb{F}_{q^k}^m) = \bigcup_{\mu \in M} (\mathrm{T} \circ f)(U_\mu^m). \qquad \square$$

In particular, with $(kt + 1)^{O(mpr)}$ evaluations of $\mathrm{T} \circ f$ one can decide if the Artin-Schreier hypersurface (8.1) contains an $\mathbb{F}_{q^k}$-rational point. Indeed, it is easy to see that the last property is equivalent to $0 \in (\mathrm{T} \circ f)(\mathbb{F}_{q^k}^m)$.

The simple estimate presented here of the sparsity of a power of a polynomial may allow to improve some results of Grigoryev & Karpinski (1991) in the case of "large" fields of "small" characteristic. If $q = p^r$, the "density" of zeros of a $t$-sparse polynomial in $t$ variables over $\mathbb{F}_q$ can be estimated from below as $(t + 1)^{-(p-1)r^2 \log p}$, and that is $t^{O(-\log^2 q)}$ for a fixed $p$, say when $p = 2$. It improves their bound $(t + 1)^{-(q-1)\log q}$, and gives a corresponding improvement of their algorithm.

OPEN QUESTION 8.4. Can the methods of Clausen et al. (1991), Grigoryev et al. (1990) help us to improve Theorem 8.2?
